Execution Context

Global, Methods, Events, Arrow Functions

Execution Context Review

- The function context is the object that owns the currently executed code
- Function context === this object
- Depends on how the function is invoked
 - Global invoke: func()
 - Object method: object.function()
 - DOM Event: element.addEventListener()
 - Using call() / apply() / bind()

Inner Method Context

const obj = {

this variable is accessible only by the outer method

```
name: 'Peter',
  outer() {
    console.log(this); // Object {name: "Peter"}
    function inner() { console.log(this); }
    inner();
obj.outer(); // Window
```

Arrow Function Context

const obj = {

this retains the value of the enclosing lexical context

```
name: 'Peter',
  outer() {
    console.log(this); // Object {name: "Peter"}
    const inner = () => console.log(this);
   inner();
obj.outer(); // Object {name: "Peter"}
```

Explicit Binding

- Occurs when call(), apply(), or bind() are used on a function
- Forces a function call to use a particular object for this binding

```
function greet() {
  console.log(this.name);
}

let person = { name: 'Alex' };
greet.call(person, arg1, arg2, arg3, ...); // Alex
```

Changing the Context: Call

 Calls a function with a given this value and arguments provided individually

```
const sharePersonalInfo = function (...activities) {
 let info = `Hello, my name is ${this.name} and`+
           + `I'm a ${this.profession}.\n`;
 info += activities.reduce((acc, curr) => {
     let el = `--- ${curr}\n`;
      return acc + el;
  }, "My hobbies are:\n").trim();
  return info;
// Continues on the next slide...
```

Changing the Context: Call

```
const firstPerson = { name: "Peter", profession: "Fisherman" };
console.log(sharePersonalInfo.call(firstPerson, 'biking',
'swimming', 'football'));
// Hello, my name is Peter.
// I'm a Fisherman.
// My hobbies are:
  --- biking
// --- swimming
// --- football
```

Changing the Context: Apply

- Calls a function with a given this value, and arguments provided as an array
- apply() accepts a single array of arguments, while call() accepts an argument list
- If the first argument is undefined or null a similar outcome can be achieved using the array spread syntax

Apply() – Example

```
const firstPerson = {
  name: "Peter",
  prof: "Fisherman",
  shareInfo: function () {
    console.log(`${this.name} works as a ${this.prof}`);
};
const secondPerson = { name: "George", prof: "Manager" };
firstPerson.shareInfo.apply(secondPerson);
// George works as a Manager
```

Changing the Context: Bind

- The bind() method creates a new function
- Has its this keyword set to the provided value, with a given sequence of arguments preceding any provided when the new function is called
- Calling the bound function generally results in the execution of its wrapped function

Bind – Example

```
const x = 42;
const getX = function () {
  return this.x;
const module = {x , getX };
const unboundGetX = module.getX;
console.log(unboundGetX()); // undefined
const boundGetX = unboundGetX.bind(module);
console.log(boundGetX()); // 42
```

Problem: Area and Volume Calculator

The functions area and vol are passed as parameters to your function

```
function area() {
  return Math.abs(this.x * this.y);
};
```

```
function vol() {
  return Math.abs(this.x * this.y *
  this.z);
};
```

Problem: Area and Volume Calculator

 Calculate the area and the volume of figures, which are defined by their coordinates (x, y and z), using the provided functions

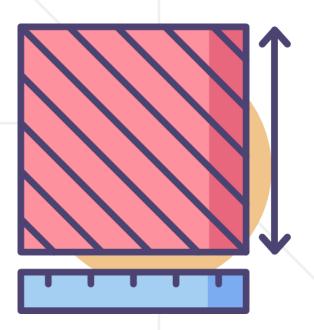

```
`[
{"x":"1","y":"2","z":"10"},
{"x":"7","y":"7","z":"10"},
{"x":"5","y":"2","z":"10"}
]`
```

Solution: Area and Volume Calculator

```
function solve(area, vol, input) {
  let objects = JSON.parse(input);
  function calc(obj) {
    let areaObj = Math.abs(area.call(obj));
    let volumeObj = Math.abs(vol.call(obj));
    return { area: areaObj, volume: volumeObj }
  return objects.map(calc);
```

Object Methods as Browser Event Handlers

```
const person = {
                                      ▼ <body>
                                        <button id="callBtn">Call Person
  name: "Peter",
                                       </body>
  respond() {
    alert(`${this.name} says hello!`);
                                                       Unwanted
const boundRespond = person.respond.bind(person);
                                                          result
documet.getElementById('callBtn')
       .addEventListener('click', person.respond);
                                                        Works as
documet.getElementById('callBtn')
                                                        intended
       .addEventListener('click', boundRespond);
```

Functional Programming in JS

First Class, Higher-Order, Pure Functions

- First-class functions are treated like any other variable
 - Passed as an argument
 - Returned by another function
 - Assigned as a value to a variable

The term "first-class" means that something is just a value. A first-class function is one that can go anywhere that any other value can go - there are few to no restrictions.

Michael Fogus, Functional Javascript

Can be passed as an argument to another function

```
function sayHello() {
   return "Hello, ";
}
```

```
function greeting(helloMessage, name) {
   return helloMessage() + name;
}
```

```
console.log(greeting(sayHello, "JavaScript!"));
// Hello, JavaScript!
```

- Can be returned by another function
 - We can do that, because we treated functions in JavaScript as a value

```
function sayHello() {
    return function () {
        console.log('Hello!');
    }
}
```

Can be assigned as a value to a variable

```
const write = function () {
   return "Hello, world!";
}
```

```
console.log(write());
// Hello, world!
```

Higher-Order Functions

 Take other functions as an argument or return a function as a result

```
const sayHello = function () {
  return function () {
    console.log("Hello!");
  }
}
```

```
const myFunc = sayHello();
myFunc(); // Hello!
```

Predicates

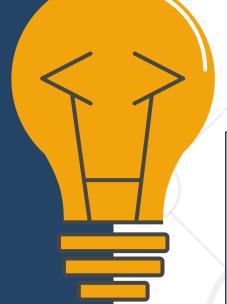

- Any function that returns a bool based on evaluation of the truth of an assertion
- Predicates are often found in the form of callbacks

```
let found = array1.find(isFound);
function isFound(element) {
   return element > 10; //True or false
}
console.log(found); // 12
```

Built-in Higher Order Functions

- Array.prototype.map
- Array.prototype.filter
- Array.prototype.reduce

Pure Functions

- Returns the same result given same parameters
- Execution is independent of the state of the system

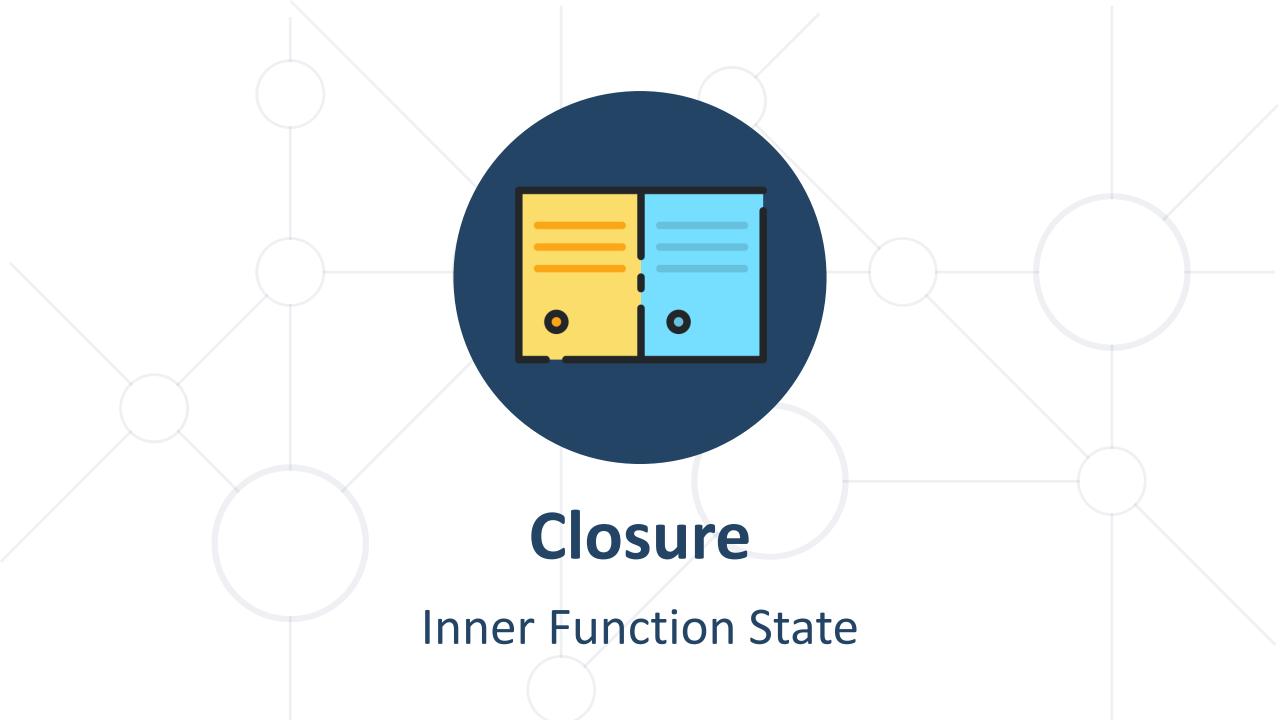

```
// impure function:
let number = 1;
const increment = () => number += 1;
increment(); // 2
// pure function:
const increment = n \Rightarrow n + 1;
increment(1); // 2
```

Referential Transparency

- An expression that can be replaced with its corresponding value without changing the program's behavior
- Expression is pure and its evaluation must have no side effects

```
function add(a, b) { return a + b };
function mult(a, b) { return a * b};
let x = add(2, mult(3, 4));
// mult(3, 4)) can be replaced with 12
```

Closure

- One of the most important features in JavaScript
- The scope of an inner function includes the scope of the outer function
- An inner function retains variables being used from the outer function scope even after the parent function has returned

Functions Returning Functions

A state is preserved in the outer function (closure)

```
const f = (function () {
    let counter = 0;
    return function () {
        console.log(++counter);
    }
})();
f(); // 1
f(); // 2
f(); // 3
f(); // 4
f(); // 5
f(); // 6
f(); // 7
```

Problem: Command Processor

- Write a program, which:
 - Keeps a string inside its scope
 - Can execute different commands that modify a string:
 - append() add str to the end of the internal string
 - removeStart() remove the first n characters
 - removeEnd() remove the last n characters
 - print() print the stored string

Solution: Command Processor

```
function solution() {
   let str = '';
   return {
      append: (s) => str += s,
      removeStart: (n) => str = str.substring(n),
      removeEnd: (n) => str = str.substring(0, str.length - n),
      print: () => console.log(str)
   }
}
```

Review: DOM Problems

 Attempt to solve problems Sections, Locked Profile and Furniture from previous exercises, by using closures to store local state and references

What is IIFE?

- Immediately-Invoked Function Expressions (IIFE)
 - Define anonymous function expression
 - Invoke it immediately after declaration

```
(function () { let name = "Peter"; })();
// Variable name is not accessible from the outside scope
console.log(name); // ReferenceError
```

```
let result = (function () {
    let name = "Peter";
    return name;
})();
// Immediately creates the output:
console.log(result); // Peter
```

Function Decoration

Partial Application and Currying

Partial Application

- Set some of the arguments of a function, without executing it
- Pass the remaining arguments when a result is needed
 - The partially applied function can be used multiple times
 - It will retain all fixed arguments, regardless of context

$$f = (x, y) \Rightarrow x + y$$

$$g = (x) \Rightarrow f(1, x)$$

$$sqr = (x) \Rightarrow Math.pow(x,2)$$

Problem: Currency Format

- Receive three primitives and a function formatter
 - The formatter function takes 4 arguments
 - Use the first three parameters of your solution to create and return a partially applied function that only takes 1 parameter
- Sample usage:

```
const dollarFormatter =
    createFormatter(',', '$', true, currencyFormatter);
console.log(dollarFormatter(5345)); // $ 5345,00
console.log(dollarFormatter(3.1429)); // $ 3,14
console.log(dollarFormatter(2.709)); // $ 2,71
```

Solution: Currency Format

```
function createFormatter(separator,
                           symbol,
                                              Partially applied
                           symbolFirst,
                                                arguments
                           formatter) {
  return (value) => formatter(separator,
                                symbol,
                                symbolFirst,
                                value);
```

Currying

Currying is a technique for function decomposition

```
function sum3(a) {
    return (b) => {
        return (c) => {
            return a + b + c;
            }
      }
}
console.log(sum3(5)(6)(8)); // 19
```

- Supply arguments one at a time, instead of at once
 - They may come from different sources
 - Execution can be delayed until it's needed

Currying Usage

- Function Composition Building new function from old function by passing arguments
- Memoization Functions that are called repeatedly with the same set of inputs but whose result is relatively expensive to produce
- Handle Errors Throwing functions and exiting immediately after an error

Currying vs Partial Application

- Currying always produces nested unary functions
- Partial application produces functions of arbitrary number of arguments
- Currying is NOT partial application
 - It can be implemented using partial application

Summary

- The execution context of a function can be changed using bind, apply and call
- JavaScript supports many aspects of the functional programming paradigm
- Closures allow a function to maintain state
 - They are powerful and flexible
- Partial application can be used to decorate and compose functions and to delay execution
